PanScience Innovation Hackathon: The Case Study Engine

Oct 31, 2026

An in-office assignment. You get the full record of one fictional eight-month client project: emails, meeting transcripts, requirements, purchase orders, change requests, the code repository, raw metric exports and feedback. Build an AI agent that turns it into a case study a buyer believes and the client's finance and legal teams would sign off. The hard part is not writing: it is working out what was really promised, what was delivered, which numbers are true, and what actually caused the results.

Why this matters

Panscience ventures win enterprise clients through proof: "we did this for a company like yours, and here is what changed." But most of our clients sign confidentiality agreements, so the best stories stay locked in email threads and project folders. Today a person spends days digging out results, guessing what is safe to say, and chasing the client for permission.

Your job: build the engine that does this in minutes. It has to follow a project over months: scope that changed, people who left, targets that were renegotiated, numbers measured in different ways at different times, and results with more than one cause. Then it has to tell that story so a buyer believes it and the client is proud to approve it.

The project library

At the start you receive the library for Project Drishti: an AI safety-camera and gate-analytics project at a fictional Indian cement plant, January to September 2026, with PredCo as the vendor. About 40 files. Everything in it is invented, and it is as messy as a real project. The table shows what each kind of source gives the story, and how it can expose the client.

Source	What it gives the case study	How it can expose the client
Contract and NDA clause	What may be said at all. Read it first: it sets the rules	It is the rule book, not a risk
Company profile of the venture	Who delivered, credentials, certifications	Low

Source	What it gives the case study	How it can expose the client
Team records	Team size, skills, who did what	Client-side names in the records
Achievement records	Awards and recognitions that back the story	An award citation that names the client
Proposal, scope of work or requirements	The "before": the client's problem in their own words, and what was promised	The client's internal project names
Purchase order	Deal size band, scope, duration	PO number, exact value, legal entity, tax IDs
Project tracker	Timeline, milestones, delays and how they were overcome	Client code names in task titles
Meeting transcripts	Objections, decisions, quotes, the moments that changed minds	Speaker names, site names, internal jargon
Email threads	Scope changes, appreciation, the human side	Signatures, domains, phone numbers
GitHub repository	What was built, architecture, scale of work	Repository and branch names, client names in code and config, URLs
KPI baselines and result reports	The before-and-after numbers	A figure so specific only one company has it
Acceptance or completion sign-off	Proof the client accepted the result	Signatory names and stamps
Photos, screen recordings, diagrams	Media for the case study	Logos, uniforms, signboards, faces, URLs on screen, location data inside image files
Client feedback	Quotes and feelings: thank-you messages, survey scores, public posts	A public post already links the client to us
Change requests, support tickets, incidents	Challenges solved; makes the story honest	Names of the client's internal systems
Invoices and payment milestones	Confirms scale and duration only	Amounts and entity names

Source	What it gives the case study	How it can expose the client
The client's public footprint	Industry context; what is already public	Harmless details that together point to one company

That last row matters most. A city, an industry and a plant size are each safe alone; together they can name the client.

What your engine must produce

One run of your engine on the library produces six things:

1. **Project story spine.** A dated timeline from first email to today: what the client asked for, what was scoped, what changed and why, what was delivered, who decided. Every line points to its file.
2. **Results sheet.** Each result with its definition, baseline, measurement window, method, final number, and what else contributed to it. Where sources disagree, which one you used and why. Show the calculation.
3. **Exposure report.** Every detail that could identify the client, alone or in combination, with the safe replacement and the contract rule behind it.
4. **The case study.** One true story told three ways, for the gatekeeper, the user and the buyer (see below).
5. **Media pack.** At least two assets you actually made, chosen for the industry, with nothing identifying in them.
6. **Approval request.** A short message to the right people at the client plus a one-page approval sheet: the exact text and media, the choices (named, anonymised, internal use only), what was changed and why, and a reply date. Write it so that saying yes is easy and good for them.

The engine itself must:

- run as a chain of agents with clear jobs, with the prompts you wrote;
- refuse any sentence or number it cannot trace to a file;
- show its working for every calculated number;
- stop for a person to approve before anything leaves the building;
- work on a different project's library without being rewritten.

The three readers

An enterprise deal needs three people to believe the story, and each reads it for a different reason. Your case study must work for all three.

	Gatekeeper	User	Buyer
Who	Procurement, IT security, legal, compliance	Plant manager, engineers, operators: the people who live with it	The person who signs: CXO, business head, owner
Their silent question	"Is this vendor safe to let in, and will I be blamed if it goes wrong?"	"Will this make my day easier, or add work and embarrass me?"	"Is it worth the money and the risk, and will it make me look good?"
What convinces them	Certifications, how data was handled, deployment model, how risks and incidents were managed	Before and after of a normal day, how long adoption took, what the team said	The business result in money or time, payback, a peer company like theirs, a path to scale
What scares them	A data leak, an audit finding, a vendor that disappears	Extra work, false alarms, being replaced	A failed project with their name on it, hidden costs
Format that works	A one-page fact sheet with evidence	A story with photos or a short video	One headline number, one slide, an ROI view

The same fact must be told three ways. Illustrative example: "false alarms fell by 70%" becomes, for the user, "operators stopped ignoring alerts"; for the buyer, "hours of downtime avoided each month"; for the gatekeeper, "no video ever left the plant network".

Bonus: the champion, the person who carries your story inside the client's company. Give them something they can forward to their boss.

Media that fits the industry

Your engine should choose the showcase from the venture's industry and the client's type, not use one template. Some starting points:

Industry	Showcase ideas	Watch out for
Manufacturing and industrial	Annotated before-and-after shop-floor photos; a "day on the line" timeline; an ROI calculator the reader fills with their own plant numbers; a 60-second animated process flow	Uniforms, machine nameplates, signboards, plant layouts
Software and developer tools	A generic redrawn architecture diagram; a before-and-after chart of release time or incidents; a screen recording on fake data; a code change walkthrough	Repository names, URLs, real data on screen
AI data and services	A gallery of synthetic sample work; a quality funnel; a process diagram	The client's own data in any sample
Government and public sector	A milestone timeline; a compliance table; scale without locations	Tender numbers, department names
Healthcare and regulated	A compliance timeline; a care journey with no patient data	Anything traceable to a patient or hospital

Formats to consider: a one-page web case study, a LinkedIn carousel, one slide for the sales deck, a short video storyboard with voice-over script, an interactive calculator.

Make at least three assets for real. Label illustrations as illustrations. Never present an AI-made photo or person as real.

How you will be judged

Four criteria, 25 points each. The judges know the library well and will check every number and claim you make against it.

Criterion	What we look for	What great looks like
Agentic workflow	How you split the work between agents and instruct them: reading months of mixed files, building the timeline, calculating results, checking claims, and where a person approves	A chain that consolidates the whole library into a traceable story spine and results sheet; refuses untraceable claims; shows its working; stops for approval; would run on another project untouched
Business understanding	What was really sold and delivered, which results matter to this client, and what the numbers are honestly worth	Scope changes and missed targets understood, not hidden; each result with its proper baseline and window; money claimed only where it was measured; credit shared where the client's own actions helped
Buyer psychology	Writing for the gatekeeper, the user and the buyer, and getting the client to say yes	Each version answers that reader's silent question and fear; the story's turning points are human, not just numbers; the approval request is safe and rewarding for the people who must sign; a real yes in the role-play
Process design	The process around the engine, from project closure to published proof	Clear triggers, owners, approval loops and records; what happens on a "no" or a later change of mind; how it handles 50 projects a year with different data

What to hand in

One shared folder named with your name:

1. The six outputs from your engine's run on the library, plus a log of any manual edits.
2. The engine: a link or screen recording of it running end to end, and every prompt or instruction you wrote for it.
3. Test results: at least 5 checks, including one where the engine should refuse a claim and one where it should stop for a person.

4. Your process on one page: who triggers the engine, who approves, what happens on a "no", how records are kept.
5. Prompt log: every prompt you gave any AI tool today, copied as you wrote it. We read this closely.
6. Pitch: at most 3 slides.

Rules

- Work alone. Use any AI tool you like; we expect you to.
- Use only the library. Invent no results, quotes or people. Mark anything estimated as ASSUMED.
- The library is fictional but treat it as confidential: do not upload it to public websites, share it, or take it home.
- Nothing goes to anyone outside the room today.
- Timings are firm. A finished, careful engine beats an unfinished clever one.
